

# Pygame Basics

**Pygame** is a set of Python modules, designed for writing video games. It runs on a variety of platforms, including Windows, Linux, and OS X. Like any modules, use `import` to access this functionality.

In order to draw objects, display images, write text, and so on, we must first create a **surface**. A surface is a two-dimensional array of pixels, each of which has a set of coordinates  $(x, y)$ . Unlike in mathematics, the top left pixel is  $(0, 0)$ , and the values of  $x$  and  $y$  increase as the surface moves right and *down*. In Pygame, an instance of the `Surface` class can be created using `set_mode(WIDTH, HEIGHT)` from the `pygame.display` module. Pygame will need to be initialized, so be sure to call `pygame.init()` at the start of any program.

Once the surface has been created, the remainder of a typical Pygame program is a loop that contains three main components: an **event loop**, which handles things like key presses and mouse clicks; code for the **game logic**, which describes the rules and structure of the game; and **drawing commands**, which display graphics on the surface. These will be discussed later.

## Basic Structure For a Pygame Program

```
1  # Imported modules, defined values and initialization
2  import pygame
3  import sys
4  from pygame.locals import *
5  pygame.init()
6  # Create a surface for drawing
7  SURFACENAME = pygame.display.set_mode((400, 300))
8  pygame.display.set_caption('My Pygame Program')
9  # MAIN GAME LOOP
10 while True:
11     # Event loop
12     for event in pygame.event.get():
13         if event.type == QUIT:
14             pygame.quit()
15             sys.exit()
16     # Game logic goes here
17     # Drawing commands go here
18     pygame.display.update()
```

Annotations in the code:

- Arrows point from the labels **Width** and **Height** to the values `400` and `300` in the `set_mode` function call on line 7.
- An arrow points from the label **Constant from pygame.locals** to the `QUIT` constant on line 13.

# Pygame Basics

---

Answer the following questions.

1. What are the coordinates of the five darkened pixels in the sample surface?
2. What is the purpose of the `while True` statement on line 10 of the Basic Structure example?

Write programs that accomplish each task, using appropriate programming conventions.

3. Create a 500 x 400 pixel surface with the caption “Hello There!”. Use the `fill()` method of `Surface` to change the background colour to blue, (0, 0, 255). Add this method call where the drawing commands should go, just before `pygame.display.update()`.
4. Create a 250 x 250 pixel surface, filled black, with the caption “Random Pixels”. Use the `set_at()` method of `Surface` to change the colour of a random pixel – from (0, 0) to (250, 250) -- to a random RGB value, such as (255, 105, 180). Watch as the surface slowly fills with coloured dots.
5. The `set_clip()` method takes four arguments (`left`, `top`, `width`, `height`) to define the area on the surface that can be drawn on (known as the **clipping area**). Modify your program above to set the clipping area to a smaller portion of the surface, to verify that portions outside of the clipping area are not coloured.
6. Using the `fill()` method, change the background colour of the surface so that it cycles through every possible RGB combination from (0, 0, 0) to (255, 255, 255). To prevent flickering, import the `time` module and call the `sleep()` method with an argument of 0.1 seconds.
