

## Transformations of Polynomial Functions

J. Garvin

Slide 1/18

## Transformations

In most cases, the graph of a function is similar to a simpler version, but may appear stretched, shifted or reflected to some extent.

The simplest version of a function that possesses all of the same characteristics of the derived function is called a *parent function* or a *base function*.

If we know information about a particular base function, it may be possible to sketch a graph of the derived function by analyzing the transformations that have been applied to the base function.

## Transformations

### Transformations of Polynomial Functions

A polynomial of the form  $f(x) = a(b(x - c))^n + d$ , where  $a$ ,  $b$ ,  $c$  and  $d$  are real constants, and  $n$  is a natural number, is a transformation of some power function  $g(x) = x^n$ .

In the form above:

- $a$  is a vertical stretch/compression, and possibly a reflection
- $b$  is a horizontal stretch/compression, and possibly a reflection
- $c$  is a horizontal translation
- $d$  is a vertical translation

Slide 3/18

## Vertical and Horizontal Transformations

Transformations may be applied vertically or horizontally.

In the function  $f(x) = a(b(x - c))^n + d$ , both  $a$  and  $d$  are vertical transformations. They appear “outside” of the function in its equation.

The parameters  $b$  and  $c$  are horizontal transformations. They appear “inside” of the function’s equation.

Horizontal transformations may appear to behave opposite to intuition: larger numbers for  $b$  compress the graph, smaller numbers stretch it, and the parameter  $c$  seems to shift the graph in the opposite direction.

Slide 4/18

## Vertical Stretches/Compressions

### Example

Sketch graphs of  $f(x) = 2x^3$  and  $g(x) = \frac{1}{3}x^3$ .

For  $f(x)$ ,  $|a| > 1$ , so it has a vertical stretch by a factor of 2. All points are twice as far from the  $x$ -axis as they are on the graph of  $y = x^3$ .

For  $g(x)$ ,  $0 < |a| < 1$ , so it has a vertical compression by a factor of  $\frac{1}{3}$ . All points are one-third as far from the  $x$ -axis as they are on the graph of  $y = x^3$ .

Slide 6/18

## Vertical Reflections

If  $a < 0$ , then a transformed power function has undergone a vertical reflection (reflection in the  $x$ -axis).

J. Garvin — Transformations of Polynomial Functions  
Slide 7/18

## Horizontal Stretches/Compressions

### Example

Sketch graphs of  $f(x) = (3x)^3$  and  $g(x) = (\frac{1}{2}x)^3$ .

For  $f(x)$ ,  $|b| > 1$ , so it has a horizontal *compression* by a factor of  $\frac{1}{3}$ . All points are three times as far from the  $f(x)$ -axis as they are on the graph of  $y = x^3$ .

For  $g(x)$ ,  $0 < |b| < 1$ , so it has a horizontal *stretch* by a factor of 2. All points are twice as far from the  $f(x)$ -axis as they are on the graph of  $y = x^3$ .

Slide 8/18

## Horizontal Stretches/Compressions

J. Garvin — Transformations of Polynomial Functions  
Slide 9/18

## Horizontal Reflections

If  $b < 0$ , then a transformed power function has undergone a horizontal reflection (reflection in the  $f(x)$ -axis).

J. Garvin — Transformations of Polynomial Functions  
Slide 10/18

## Vertical and Horizontal Translations

### Example

Sketch a graph of  $f(x) = (x - 2)^3 + 3$ .

The graph of  $f(x)$  has two transformations: a horizontal translation 2 units to the *right*, and a vertical translation 3 units up.

Neither transformation affects the shape of the graph, only its position.

## Identifying Transformations From an Equation

### Example

Identify the base function, and the transformations applied to it, to create the function  $f(x) = 2(3x - 1)^3 - 5$ .

The base function is  $y = x^3$ .

The 2 indicates a vertical stretch by a factor of 2.

The 3 indicates a horizontal compression by a factor of  $\frac{1}{3}$ .

There is a horizontal translation  $\frac{1}{3}$  of a unit to the right, since the equation can be written  $f(x) = 2(3(x - \frac{1}{3}))^3 - 5$ .

Finally, there is a vertical translation down 5 units.

## Graphing Transformed Functions

### Example

Sketch a graph of  $f(x) = -2(x - 1)^4 + 3$ .

The base power function,  $y = x^4$ , has Q2-Q1 end behaviour and its "vertex" at the origin.

$f(x)$  has a vertical reflection, so its end behaviour is Q3-Q4.

There is a vertical stretch by a factor of 2, a horizontal translation 1 unit to the right, and a vertical translation 3 units up.

## Graphing Transformed Functions

## Determining Equations From Graphs

### Example

Determine an equation for the function shown below.

## Determining Equations From Graphs

The function has Q2-Q4 end behaviour, so it has an odd degree (likely cubic) and negative leading coefficient.

The "pivot point" of the function is at  $(2, 4)$ , indicating a vertical translation up 4 units and a horizontal translation right 2 units.

To determine if a vertical stretch has occurred, note that the function has an  $f(x)$ -intercept at 6.

To go from  $(2, 4)$  to  $(0, 6)$ , there is a vertical change of 2 for a horizontal change of 2.

For the parent function  $y = x^3$ , there is a horizontal change of 2 from  $(0, 0)$  to  $(2, 8)$ , resulting in a vertical change of 8.

Thus, there is a vertical compression by a factor of  $\frac{1}{4}$ .

A possible equation, then, is  $f(x) = -\frac{1}{4}(x - 2)^3 + 4$ .

## Questions?
